# Affinity groups according to individual preferences 

Alain Guénoche

CNRS, Institut de Mathématiques de Marseille<br>alain.guenoche@univ-amu.fr

Avignon, 2016

## Problem

Let $X=\{n$ individuals $\}$

- $x_{+}$(ranked) list of those $x$ would like to be with
- $x_{-}$(ranked) list of those $x$ rejects out of his group
$\{2 n$ lists $\} \rightarrow$ Affinity values ( $\geq 0$ and $<0$ ), non symmetrical

$$
a: X \times X \rightarrow \mathbb{Z}
$$

Pb : Compute a partition of $X$ in $p$ classes

- satisfying (at the best) affinity preferences
- in (more or less) balanced classes

## Many applications

- built teams in business companies
- spread workers in workshops or offices
- make working groups .. at school

Partition $\Rightarrow$ Equivalence Relation $\Rightarrow$ Make affinities symmetrical

- If there is a rejection iff $a(x, y)<0$ or $a(y, x)<0$

$$
A(x, y)=\min \{a(x, y), a(y, x)\}
$$

- Else, there in an attraction : $a(x, y) \geq 0$ and $a(y, x) \geq 0$

$$
A(x, y)=\frac{1}{2}[a(x, y)+a(y, x)]
$$

## A primary classroom $(n=25)$

- At most 3 (ordered) attractions ( $>0$ ) and rejections ( $<0$ )
- weighted $\pm(3,2,1)$, indifference $=0$

## Multicriteria Optimization Problem

Let $P=\left\{X_{1}, X_{2}, \ldots, X_{p}\right\}$ be a partition on $X$

1. Rejections first

- An undirected rejection graph
- A coloring problem

$$
R(P)=\sum_{k=1}^{p} \sum_{x, y \in X_{k}, A(x, y)<0}-A(x, y)
$$

2. Combining rejections and attractions

$$
W(P)=\sum_{k=1}^{p} \sum_{x, y \in X_{k}} A(x, y)
$$

## The rejection graph of the CE2 classroom

A clique of order $4\{3,4,5,18\} \Rightarrow \chi \geq 4$

## Rejections first

Coloring the rejection graph
Optimal coloring NP-Hard $\Rightarrow$ Heuristic Dsatur (Brelaz 1979)

$$
\operatorname{Sat}(x)=\mathrm{Nb} . \text { of colors in } \Gamma(x)
$$

While vertices are not colored
Select $x$ with maximum Sat value then maximum degree
Color $x$ with the first possible color
For any $y$ adjacent to $x$
$y$ is saturated for this color
$D g(y):=D g(y)-1$
Update Sat(y)

## Equitable classes

Dsatur has been extended to an optimal coloring (Brelaz, 1979)
but
Classes are not balanced
Equitable coloring problem :

$$
\forall\{i, j\},\left|\operatorname{card}\left(X_{i}\right)-\operatorname{card}\left(X_{j}\right)\right| \leq 1
$$

I.L.P. (C. Ribero et al., 2014), B \& B (Mendez-Diaz et al., 2015)

$$
\forall p, \exists G \text { such that } \chi(G)=2 \text { and } \chi_{e q}(G)>p
$$

## Balancing classes

1. Balancing procedure (optimizing $W$ )

While (gainmax $>0$ )
For all $x$
For any class without rejection of $x$
Let $P^{\prime}$ be the partition after $x$ transfer
Dif $=W\left(P^{\prime}\right)-W(P)$
$\operatorname{gain}(x):=\operatorname{Max}($ Dif $)$
gainmax := Max (gain(x))
If (gainmax $>0$ ) transfer $x$
2. Modify Dsatur

Colour $x$ with the less used possible color

## Pupil groups by Dsatur + Balancing procedure

Four groups ( $R=0$ and $W=37.5$ )

## Simulations I

Two strategies

1. Applying Dsatur + Balancing procedure
2. Applying Modified Dsatur + Balancing procedure

For random affinity graphs with 100 vertices

| $N_{r}$ | $W_{1}$ | \% Equi | 4 | 5 | 6 | $W_{2}$ | OEqui $_{2}$ | 4 | 5 | 6 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3 | 93.8 | 75 | 94 | 6 | 0 | 74.6 | 83 | 90 | 10 | 0 |
| 4 | 139.7 | 73 | 0 | 98 | 2 | 103.9 | 89 | 1 | 98 | 1 |
| 5 | 177.0 | 69 | 0 | 60 | 40 | 141.9 | 62 | 0 | 49 | 51 |

$N_{r}$ : Nb. of attractions and rejections per vertex
$W_{i}$ : Affinity weights
\% Equi $i_{i}$ : Equitable partition rate (cardmax - cardmin $\leq 1$ )
4,5,6 : Percentage of Pb . giving 4, 5, 6 classes

## How far is Dsatur from $\chi$ ?

Applying

1. Strict Dsatur + Balancing procedure
2. Modified Dsatur + Balancing procedure to random graphs with 100 vertices and $\chi=5$

| $N_{a}$ | $\%$ Equi $_{1}$ | 5 | 6 | 7 | 8 | 9 | $\%$ Equi $_{2}$ | 5 | 6 | 7 | 8 | 9 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 200 | 100 | 100 | 0 | 0 | 0 | 0 | 100 | 100 | 0 | 0 | 0 | 0 |
| 400 | 83 | 97 | 3 | 0 | 0 | 0 | 98 | 99 | 1 | 0 | 0 | 0 |
| 600 | 93 | 0 | 88 | 12 | 0 | 0 | 96 | 0 | 78 | 22 | 0 | 0 |
| 800 | 73 | 0 | 5 | 71 | 24 | 0 | 84 | 0 | 2 | 59 | 38 | 1 |
| 1000 | 47 | 6 | 0 | 9 | 55 | 30 | 44 | 6 | 2 | 7 | 57 | 28 |

$N_{a}$ : Nb. of edges per graph
\%Equi : percentage of Equitable partitions
percentage of Pb . with $5,6,7,8$ or 9 groups

## Combining attractions and rejections

Optimizing

$$
\max _{P \in \mathcal{P}} W(P)=\sum_{k=1}^{p} \sum_{(x, y) \in X_{k}} A(x, y)
$$

A classical NP-Hard problem for graph (network) partitioning

- when vertex paires are valued by Modularity
- with positive and negative values
- Hierarchical ascending method (Girwan \& Newmann, 2002)
- Random walk (Pons \& Latapy, 2006)
- The Louvain method (Blondel et al. 2008)
- Bootstrap clustering (Gambette \& Guénoche 2011)
- etc ..

## Two simple algorithms

1. Hierarchical ascending method:

- Starting from the atomic partition
- merge two classes making maximum affinity gain
- until the required nb. of classes

2. Transfert method (as Louvain)

- Start from a balanced (random) partition
- Transfer vertex making maximum affinity gain (W)
- while there is a > 0 gain
$+$
Balancing procedure and Rejection elimination procedure

## Eliminating rejections

Rejection elimination procedure
While (gainmax >0)
For all $x$ rejected in its class $c$
$R(x):=$ Sum of the $x$ rejection weights in $c$
For any other class $q$
Let $R^{\prime}(x)$ the $x$ rejection weights in $q$ Dif $=R^{\prime}(x)-R(x)$ $\operatorname{gain}(x):=\operatorname{Max}_{q}\{\operatorname{Dif}\}$
gainmax $:=\operatorname{Max}_{x}\{\operatorname{gain}(x)\}$
If (gainmax $>0$ ) transfer $x$ into class $q$

## Other pupil groups

Four better groups ( $R=0$ et $W=45.0$ )

## Simulation II

Random affinity graphs with 100 vertices

- $N_{r}$ attractions and rejections
- $p$ classes are expected

| $N_{r}$ | $p$ | $W_{1}$ | $G^{2} p_{1}$ | $R_{1}$ | $W_{2}$ | $G a p_{2}$ | $R_{2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 3 | 4 | 113.4 | 4.1 | 6.5 | 109.4 | 3.4 | 5.9 |
| 4 | 5 | 168.0 | 4.0 | 4.3 | 164.7 | 3.4 | 4.1 |
| 5 | 5 | 206.8 | 4.0 | 14.4 | 209.7 | 3.6 | 12.9 |
| 5 | 6 | 225.6 | 4.3 | 3.2 | 221.4 | 3.5 | 3.3 |

W:Affinity weights
Gap : Difference between the largest and the smallest classes $R$ : Average rejection weights (on the whole graph)

## Conclusions

If rejections are mandatory (and can be satisfied) Dsatur strict + Balancing procedure give

- few classes
- a good equilibrium
- but smallest affinity weights

If rejections are not mandatory
Optimizing affinity weights gives better results The transfer method produces

- classes which are better balanced (in the average)
- less rejections
